Theory Claims

• **Proposition: proxy coverage controls drift**

If the verifier proxy covers every relevant mode, the accepted sample distribution remains close to the target:

$$W_2(\widehat{\mathcal{D}}_t, \mathcal{D}^*) \leq \epsilon_{\text{proxy}} + \epsilon_{\text{sample}}.$$

• **Theorem: collapse is avoided under coverage**

Under bounded replacement and nonzero mode recall,

$$\Pr[m \in \text{supp}(\widehat{\mathcal{D}}_t)] \geq 1 - \delta, \quad t \leq T.$$

The conclusion drives the center claim.

• **Proposition: global witnesses are required**

A local acceptance rule becomes safe only when every tail region has at least one witness in the proxy set.

• **Theorem: rank evidence before decoration**

Keep theorem statements, assumptions, and equations visible; move backup derivations behind the QR link.

Extraction Rule

Conclusion: a locally simple selection rule can preserve rare modes when its proxy covers the population before replacement begins.

Coverage saves tails.
Selection remains safe.
Global witnesses
restore missing modes.
Before replacement.

Mock Evidence

- Coverage audit flags missing tail modes.
- Replacement budget stays below the risk threshold.
- Proxy update recovers the omitted group.

Result Slot

Use this slot for the single figure that most directly supports the conclusion, not for a dense paper screenshot.

Decision Notes

The right column explains why the central claim is credible: strongest evidence first, then one robustness check, then one boundary condition.
